Abstract: This paper presents a very efficient design procedure for a high-performance microstrip lowpass filter (LPF). Unlike many other sophisticated design methodologies of microstrip LPFs, which contain complicated configurations or even over-engineering in some cases, this paper presents a straightforward design procedure to achieve some of the best performance of this class of microstrip filters. The proposed filter is composed of three different polygonal-shaped resonators, two of which are responsible for stopband improvement, and the third resonator is designed to enhance the selectivity of the filter. A holistic performance assessment of the proposed filter is presented using a Figure of Merit (FOM) and compared with some of the best filters from the same class, highlighting the superiority of the proposed design. A prototype of the proposed filter was fabricated and tested, showing a 3-dB cut-off frequency (f_c) at 1.27 GHz, having an ultrawide stopband with a suppression level of 25 dB, extending from 1.6 to 25 GHz. The return loss and the insertion loss of the passband are better than 20 dB and 0.25 dB, respectively. The fabricated filter has a high FOM of 76331, and its lateral size is 22.07 mm \times 7.57 mm.

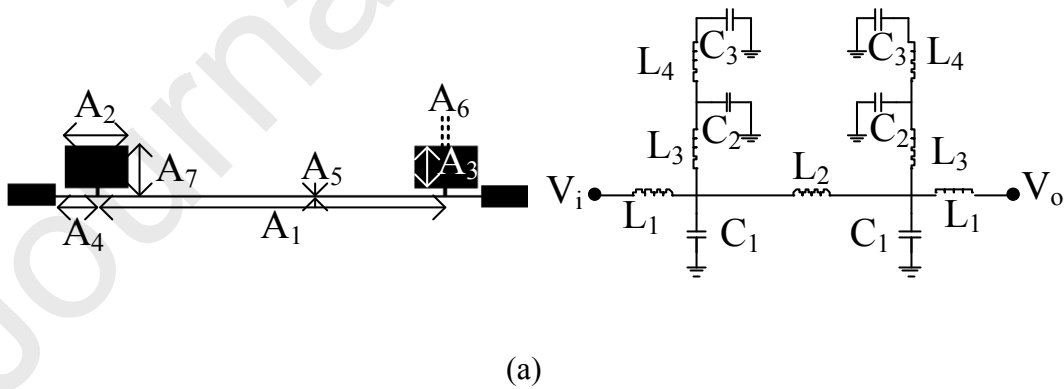

Introduction: Microstrip technology has been extensively used for implementation of microwave passive and active components, due to its low-cost fabrication process and its versatile characteristics [1-6]. Microstrip filters (LPFs) play a critical role in modern communication systems for suppressing unwanted harmonics, as they are easily integrated with other microwave components. Therefore, passive LPFs with a small size, wide stopband, and low cost are highly in demand [7]. Such high-performance filters will play a significant role in the upcoming new generation of the low-cost satellite communications technology, where the size and the cost of the Earth receiver stations are critical. This is even more important for the

communication-one-the-move, where in addition to all strict satellite communication requirements, there is a strong motivation to employ passive, affordable microwave and electromagnetic components in the portable satellite receivers [8-11]. Thus, various techniques have been studied to achieve LPFs with the mentioned features [12-27]. A modified version of T-shaped resonators in conjunction with multiple open-stubs was proposed in [12] to realize a compact LPF with a large stopband. In a different approach, a new E-type feeding structure was proposed to feed a cross-shaped patch resonator to minimize the passband insertion loss [13]. Coupled rhombic stubs were proposed in [14] to improve both stopband and out-of-band rejection. While the design procedures in [12], [14] have been successful in some factors of merit, their roll-offs were reported to be around 50 dB/GHz. To achieve high selectivity, tapered sectorial resonators and large radial stubs were proposed in [15] and [16], respectively. Despite the very sharp responses realized in these two works, both procedures resulted in a relatively large circuit size. Other methods, such as stepped-impedance [13-17], pendulum-shaped resonator [18] and spiral lines [19], have been proposed for wide-stopband applications. Similar out-of-band performance along with a strong harmonic attenuation can be achieved using defected ground structures [20, 21]; however, the implementation complexity is considered as the associated challenge with this technique.

In [22], a high-impedance transmission-line is loaded by multiple compact microstrip resonant cells to provide both high selectivity and wide stopband, while the circuit size is not equally weighted, resulting in a relatively large filter. In [23-27], numerical-based approaches were used to predict the transfer function of a lowpass filter and to extract its resonant frequencies. With the development of nature-based optimization algorithms, such as ant colony optimization [28-29], neural networks [30-34] and particle swarm optimization [35-36], a new avenue of research in the microwave and electromagnetic community has been established,

where several customized optimization algorithms in conjunction with electromagnetic (EM) simulators have been used to design and optimize a wide range of microwave and EM components, such as filters, power dividers, frequency selective surfaces [37-44]. Apart from the above-mentioned applications, microstrip LPFs are integrated with other microwave components, such as power-dividers with harmonic suppression capability [45-46]. In [47], a symmetric LPF composed of several square resonators was used to attenuate the reflected signals throughout the passband up to 15 dB, whereas the transition band is relatively large. Defected ground structure (DGS) has been reported as another technique for harmonic suppression in LPFs, considerably extending the stopband range [48],[49]. However, the attenuation level in the stopband of these filters are less than 18 dB, and the return loss in the passband is around only 10 dB. Also, radial-shaped and semi-circle patch resonators were applied in [50], even though it suffers from a narrow stopband. Reviewing related literature reveals that most approaches mainly focus on improving one or some of the critical properties of the LPFs, while other aspects, particularly design complications, are sacrificed or neglected. Hence, we propose a very simple, yet systematic design methodology, to reasonably satisfy all factors of merit and achieve a significantly greater FOM than many recently published LPFs. The presented filter is compact with total area of only $0.0048 \lambda_g^2$, where λ_g is the guided wavelength at the cut-off frequency. The measured transition band extends from 1.27 GHz to 1.67 GHz with attenuation levels of -3 and -40 dB, respectively. The spurious signals are significantly suppressed from 1.6 GHz up to 25 GHz, which is about $19f_c$. The proposed LPF operating at 1.27 GHz with wide stopband and miniaturized dimensions is a good candidate for the satellite communication technology. All simulations are carried out by ADS Momentum on an RT-5880 substrate with a thickness of 0.381 mm.

Filter Design: The proposed procedure is composed of three steps, delivering three different cells with different functionalities essential for the filter design. First, a wideband suppressing cell with a high attenuation level is designed to ensure the wide-stopband capability of the filter. To do this, a pair of T-shaped resonators is placed on a high-impedance transmission line, as shown in Fig. 1(a). In this figure, V_i and V_o represent the input and output signals. The proposed structure is modeled by a LC equivalent circuit to verify the suppression capability. In addition to the LC model analysis, even and odd mode analysis can be used to justify the filtering behavior of the microstrip filters as explained in [51], [52]. In LC model proposed, L_1 , L_2 and C_1 are inductances and capacitance of the transmission line, respectively. L_3 and C_2 denote the inductance and capacitance of the high impedance lines of the T-shaped resonators, respectively. The inductance and capacitance of the low impedance stub are introduced by L_4 and C_3 , respectively. Lumped-element values are calculated and optimized using the methods described in [7,16]. The LC values of the resonator are as follows: $C_1=0.24$ pF, $C_2=0.28$ pF, $C_3=0.24$ pF, $L_1=1.62$ nH, $L_2=4.2$ nH, $L_3=0.25$ nH and $L_4=0.4$ nH. This cell is designed to create a deep transmission zero at 12 GHz with an ultrawide stopband.

(b)

Fig. 1 The proposed wideband suppressing cell. (a) Layout and LC equivalent circuit. (b) EM and LC simulation results.

Fig. 1 (b) shows the EM and LC responses. To analyze and verify the operation of the LC model, transfer function of the T-shaped resonators is computed as (1). The formula of the first transmission zero (Tz_1) is attained by equating the transfer function to zero as (2). Notice, r is the matching impedance of input and output ports ($r = 50\Omega$). As seen, the equation of Tz_1 is related to LC parameters, so that its location can be easily relocated by varying LC values.

$$\frac{v_o}{v_i} = \frac{2rd}{dL_1s + L_1s(cL_1s + b + d) + L_2s(cL_1s + d) + r^2ad + adrL_1s + 2r + rcL_1s + rcL_2s + 2rd}, \quad (1)$$

where

$$a = \left(\frac{2cd + c^2L_2s}{d^2} \right),$$

$$b = \left(L_1 s + L_2 s \left(\frac{c L_1 s}{d} + 1 \right) \right) c,$$

$$c = C_1 C_2 C_3 L_3 L_4 s^5 + (C_1 C_2 L_3 + C_1 C_3 L_3 + C_1 C_3 L_4 + C_2 C_3 L_4) s^3 + (C_1 + C_2 + C_3) s,$$

$$d = C_2 C_3 L_3 L_4 s^4 + (C_2 L_3 + C_3 L_3 + C_3 L_4) s^2 + 1.$$

$$T_{z1} = \left| \frac{\sqrt{\frac{C_2 L_3 + C_3 L_3 + C_3 L_4 - \sqrt{(C_2 L_3 + C_3 L_3 + C_3 L_4)^2 - 4 C_2 C_3 L_3 L_4}}{2 C_2 C_3 L_3 L_4}}}{2\pi} \right|. \quad (2)$$

Location of T_{z1} is related to the LC values, particularly the values of L_3 , L_4 and C_3 which represent the T-shaped resonators equivalent model. Fig 2 shows the effects of varying L_4 , L_3 and C_3 . The sweep range of L_3 and L_4 is 0 to 1 nH and the sweep range of C_3 is between 0 to 1 pF. As can be seen, by decreasing the values of L_4 and L_3 , T_{z1} shifts to higher frequencies, extending the stopband, while the cut off frequency is less affected by variation of L_4 compared to L_3 . The next parameter which is effective to alter stopband range is C_3 . According to Fig 2, it is seen that decreasing the value of C_3 increases the stopband and cut off frequency. It should be noticed that for swept values of L_4 , L_3 and C_3 only the one parameter is swept and the others are fixed

(a)

(b)

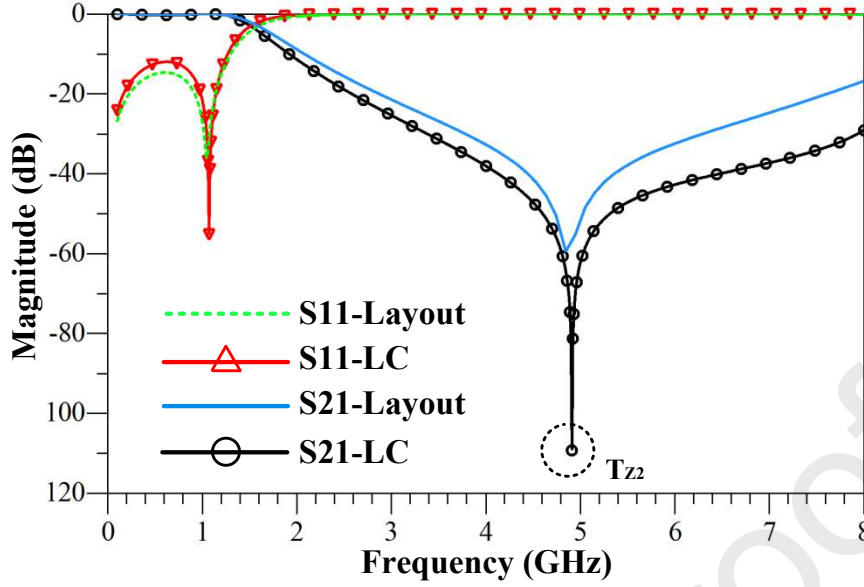

(c)

Fig. 2. Variation of Tz_1 and its effects on the frequency response of the filter versus the different values of L_4, L_3 and C_3 .

Octagonal Resonator: In the second step, another suppression cell is designed with the advantage of providing a smaller transition band. This characteristic contributes to a higher selectivity in the filtering mechanism of the proposed LPF. To do so, an octagonal resonator along with its LC model with a transmission zero tuned at 5 GHz is designed and shown in Fig. 3.

(a)

(b)

Fig. 3 Octagonal suppression cell. (a) Layout and equivalent circuit. (b) EM and LC simulation results.

In the LC model, the inductor and the capacitor associated with the transmission line are represented by L_5 and C_4 , respectively. L_6 and C_5 are inductance and capacitance of the high-impedance line of octagonal resonator, respectively. In addition, the capacitor and the inductor of the octagonal-shaped stub are C_6 and L_7 , respectively. The values of the lumped elements of the octagonal resonator are as follows: $C_4=0.27$ pF, $C_5=1.08$ pF, $C_6=1.49$ pF, $L_5=8.51$ nH, $L_6=0.17$ nH, $L_7=0.50$ nH. The suppression performance of the proposed cell is verified by its EM and LC responses in Fig. 3. The transfer function of the octagonal resonator and the equation of T_{z_2} are calculated and represented in (3) and (4), respectively.

$$\frac{v_o}{v_i} = \frac{2r}{L_5 S (L_5 C_4 S^2 + b + 1) + r (L_5 C_4 S^2 + a L_5 S + b + 2) + r^2 a + L_5 S}, \quad (3)$$

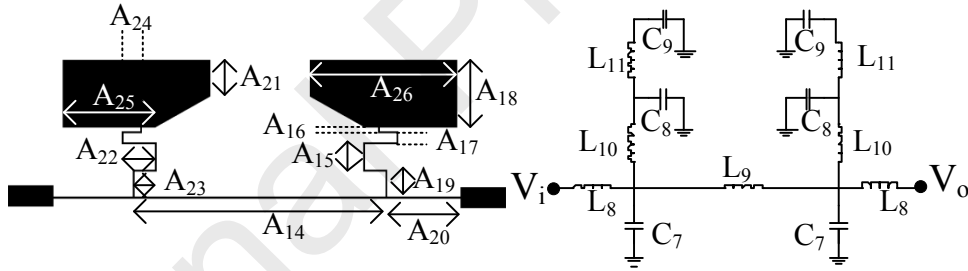

where

$$a = \left(\frac{C_5 C_6 L_7 S^3 + (C_5 + C_6) S}{C_5 C_6 L_7 L_6 S^4 + (C_5 L_6 + C_6 L_6 + C_6 L_7) S^2 + 1} + C_4 S \right),$$

$$b = \left(\frac{L_5 S (C_5 C_6 L_7 S^3 + (C_5 + C_6) S)}{C_5 C_6 L_7 S^4 + (C_5 L_6 + C_6 L_6 + C_6 L_7) S^2 + 1} \right).$$

$$T_{Z2} = \sqrt{\frac{C_5 L_6 + C_6 L_6 + C_6 L_7 - \sqrt{(C_5 L_6 + C_6 L_6 + C_6 L_7)^2 - 4 C_5 C_6 L_6 L_7}}{2 C_5 C_6 L_6 L_7}} \cdot \frac{1}{2\pi} \quad (4)$$

In the third step, the desired cut-off frequency of the filter is realized using a very-sharp-response cell. So, two pentagonal resonators are proposed to introduce a significantly deep transmission zero, placed very close to the desired cut-off frequency, as shown in Fig. 4.

(a)

(b)

Fig. 4 Pentagonal resonators. (a) The layout and the equivalent circuit. (b) The EM and LC simulation results.

As can be seen from the LC and EM responses, there is a strong transmission zero at 2 GHz, due to the identical pentagonal resonators. In the LC model of pentagonal resonators, L_8 , L_9 and C_7 show inductances and capacitance of the transmission line, respectively. L_{10} and C_8 are inductor and capacitor of the high-impedance lines of the pentagonal resonators, respectively. The inductor and capacitor of the pentagonal-shaped stubs are depicted by L_{11} and C_9 , respectively. The values of the lumped elements are as follows: $C_7=0.24$ pF, $C_8=0.77$ pF, $C_9=1.16$ pF, $L_8=3.32$ nH, $L_9=10.26$ nH, $L_{10}=4.36$ nH, $L_{11}=0.08$ nH. The formula of T_{z3} is obtained as (6) using transfer function of pentagonal resonators in (5). The physical dimensions of the proposed LPF are classified in Table 1.

$$\frac{v_o}{v_i} = \frac{2rd}{dL_8s + L_8s(cL_8s + b + d) + L_9s(cL_8s + d) + r^2ad + adrL_8s + 2r + rcL_8s + rcL_9s + 2rd}, \quad (5)$$

where

$$a = \left(\frac{2cd + c^2L_9s}{d^2} \right),$$

$$b = \left(L_8s + L_9s \left(\frac{cL_8s}{d} + 1 \right) \right) c,$$

$$c = C_7C_8C_9L_{10}L_{11}s^5 + (C_7C_8L_{10} + C_7C_9L_{10} + C_7C_9L_{11} + C_8C_9L_{11})s^3 + (C_7 + C_8 + C_9)s,$$

$$d = C_8C_9L_{10}L_{11}s^4 + (C_8L_{10} + C_9L_{10} + C_9L_{11})s^2 + 1.$$

$$T_{Z3} = \frac{\sqrt{-\frac{C_8L_{10} + C_9L_{10} + C_9L_{11} - \sqrt{(C_8L_{10} + C_9L_{10} + C_9L_{11})^2 - 4C_8C_9L_{10}L_{11}}}{2C_8C_9L_{10}L_{11}}}}{2\pi}. \quad (6)$$

Table 1: The physical dimensions of the proposed LPF

Parameter	A ₁	A ₂	A ₃	A ₄	A ₅	A ₆	A ₇	A ₈	A ₉
Value (mm)	17.8	3.3	2.2	1.8	0.1	0.2	2.6	10.7	1.7
Parameter	A ₁₀	A ₁₁	A ₁₂	A ₁₃	A ₁₄	A ₁₅	A ₁₆	A ₁₇	A ₁₈
Value (mm)	4.9	10.8	5.3	5.30	13.6	1.6	0.3	0.7	3.7
Parameter	A ₁₉	A ₂₀	A ₂₁	A ₂₂	A ₂₃	A ₂₄	A ₂₅	A ₂₆	
Value (mm)	1.5	4.0	2.0	1.8	1.2	1.0	5.0	8.0	

The current distributions of the final structure at the cut off frequency (1.27 GHz) and a typical frequency in the stopband (3.21 GHz) are plotted in Figs. 6a and 6b. As observed, the current density is stronger at 1.27 GHz and the flow is suppressed at the stopband.

Fig. 5. Current distributions of the proposed LPF. (a) Cut-off frequency (1.27 GHz), (b) Stopband area (3.21 GHz)

Measurement Results: To verify the presented design approach, a prototype LPF was fabricated and measured, as shown in Fig. 6a. The fabricated model is implemented on an RT-5880 substrate with a thickness of 0.381 mm. The S-parameters of the filter were measured using an Agilent vector network analyzer (E8361 C) and shown in Fig. 6b. Fig. 6c shows the variation of group delay (GD) throughout the passband is only 0.7 ns, depicting a flat response. According to these figures, the frequency response of the proposed filter has a 3-dB cut-off frequency of 1.27 GHz with a very small transition band. The filter exhibits excellent in-band and out-of-band characteristics, providing a super ultrawide stopband, extending from 1.6 GHz up to 25 GHz, which is about $19f_c$. The return loss and the insertion loss in the passband are better than 20 dB and 0.25 dB, respectively, showing a flat and stable passband. The filter is compact, with a size of $0.12\lambda_g \times 0.04\lambda_g$ (where λ_g is the guided wavelength at 1.27 GHz). Table 2 summarizes a comparison between some of the newly reported LPFs and the proposed one, based on the specifications explained in [16] and [23].

[48]	100	1.6	1.8	0.032	1	9000	12
[49]	37.2	1.62	1.5	0.18 × 0.21	1	2391	10
[50]	14	1.5	1.5	0.06 × 0.08	1	6468	15
<i>This work</i>	92.5	1.76	2.5	0.04 × 0.12	1	76,331	20

In table 2, the roll-off rate (ξ) is defined as:

$$\xi = \frac{\alpha_{max} - \alpha_{min}}{f_s - f_c} \quad (dB/GHz) \quad (7)$$

where α_{max} and α_{min} show the suppression level of -40 dB and -3 dB. Also, the frequencies corresponding with the suppression levels of -40 dB and 3 dB are f_s and f_c , respectively. The relative stop-band width (RSB) is given by :

$$RSB = \frac{\text{stopband width}}{\text{cut off frequency}} \quad (8)$$

The suppression factor (SF) is:

$$SF = \frac{\text{suppression level in stopband}}{10} \quad (9)$$

The normalized circuit size (NCS) is:

$$NCS = \frac{\text{physical size (length} \times \text{width)}}{\lambda_g^2} \quad (10)$$

where λ_g is the guided wavelength at 1.27 GHz and for 2 dimensional structure the architecture factor (AF) is defined 1. Finally, the FOM is defined as:

$$FOM = \frac{RSB \times \xi \times SF}{AF \times NCS} \quad (11)$$

Conclusion: A highly selective, compact LPF with an ultrawide stopband is designed through a systematic approach. In this approach, three polygonal resonators are designed, where two resonators are collectively responsible for providing an ultrawide stopband, and the third resonator independently controls the cut-off frequency of the filter with a sharp roll-off. The filter suppresses all spurious bands up to the 19th harmonic, with a very good attenuation of 25 dB, exhibiting an excellent out-of-band characteristic. The fabricated LPF has a high return loss (20 dB) and negligible insertion loss (0.25 dB) in the passband. The filter is compact with a very high FOM of 76,331.
