This article has been withdrawn by Sagartirtha Sarkar, Douglas W. Leaman, Parames Sil, Annitta Morehead, Debabrata Mukherjee, Joe Hollyfield, and Subha Sen. Sudhiranjan Gupta, David Young, Norman Ratliff, Yaping Sun, and Mary Rayborn could not be reached. The images from 1-year-old mice shown in Fig. 1A were reused in the subsequent JBC article Sarkar, S., *et al.* (2004) *J. Biol. Chem.* **279**, 52630–52642 as 9-month-old mice. The images shown in Fig. 1C (*II*) as 18-week-old mice were also reused in the same publication (Sarkar, S., *et al.* (2004) *J. Biol. Chem.* **279**, 52630–52642) as 9-month-old mice. The GAPDH immunoblot shown in Fig. 2B (1) was reused in Sarkar, S., *et al.* (2004) *J. Biol. Chem.* **279**, 52630–52642. The withdrawing authors do not agree to the Journal's decision as the concerned images of Fig. 1 were reused in the second JBC article (Sarkar, S., *et al.* (2004) *J. Biol. Chem.* **279**, 52630–52642) only to introduce the model in that article as per the reviewer's suggestion, and no new data were put forward using these image panels. The withdrawing authors also disagree with the Journal's statement of the reuse of the GAPDH immunoblot. The withdrawing authors requested the journal to not withdraw this publication because no data in this particular article are in question and the subsequent JBC article (Sarkar, S., *et al.* (2004) *J. Biol. Chem.* **279**, 52630–52642) is to be withdrawn by the authors for the same figure panel duplication. The request was however declined by the Journal. The withdrawing authors have pointed out that the above-referenced article was 17 years ago, and their original documents were not saved after 15 years. In the absence of original data and figures, the withdrawing authors were unable to meet the criteria for the Journal. The withdrawing authors stand by the results and conclusions of this article and state that no data in this particular article were compromised in any way.

with the age-matched WT mice. The heart weight/body weight (HW/BW) ratio also increased significantly in all Tg mice during the progression to hypertrophy (Fig. 1, A-B). All four lines of mice displayed myotrophin overexpression and developed significant hypertrophy, which eventually led to heart failure.

At ~36 weeks of age, the Tg mice, which overexpress cardio-specific myotrophin, developed symptoms of heart failure, including lethargy, edema, pulmonary effusion, and lack of alertness. The kidneys of the Tg mice did not differ from those of WT mice (Table I).

Myotrophin Overexpression Was Associated with Histologic Lesions in Heart Tissues of Tg Mice

The LV heart walls of Tg mice (18 weeks old) were severely thickened compared with those of WT mice (Fig. 1C (I–III)) and showed concentric hypertrophy (Fig. 1C (I)). Both right and left ventricles of the Tg mice were enlarged and displayed increased septal thickness compared with those of the WT mice. Histology examination showed typical large nuclei in the Tg group, confirming myocyte hypertrophy (Fig. 1C (I)). Foci of classic myocyte disarray were observed in the Tg heart tissue, a change not present in the WT mice. Fibrotic foci accompanied by dystrophic calcification were observed in the Tg mice but were absent in the WT mice (III). Small foci of apparent atherosclerosis were observed in the coronary vessels.

Myotrophin Is Overexpressed in Heart Tissues

Myotrophin mRNA (Fig. 2A (1)) was increased in the hearts of Tg mice through four generations compared with WT mice. When regression analysis was done between myotrophin mRNA expression and HW/BW in WT and Tg mice (age ranging from 18 to 24 weeks) from all four lines, a linear correlation between myotrophin gene expression and HW/BW was observed (Fig. 2A (2); $y = 14.916x + 8.9615$ and $r^2 = 0.9691$ for Tg; $y = 15.209x - 15.744$ and $r^2 = 0.9227$ for WT). Fluorescein isothiocyanate-tagged myotrophin was abundant and distinctly visible in the myocytes from 24-week-old Tg mice from all lines, compared with age-matched WT (Fig. 2B (3)). However, myotrophin mRNA expression in the kidneys, livers, and lungs of Tg mice did not differ from that in WT mice (data not shown). As a consequence of myotrophin gene overexpression, expression of both hypertrophy marker genes (ANF and β -MHC) and proto-oncogenes (*c-fos*, *c-jun*, and *c-myc*) were also up-regulated in all four generations of the Tg mice lines (Fig. 2, C and D).

Myotrophin Overexpression Leads to Myocyte Hypertrophy in Tg Mice

To document myotrophin overexpression-induced changes in myocytes, we quantitated myocyte dimension by hematoxylin/eosin staining of heart tissue and image scanning using the Image Pro Plus software program. The cross-sectional area of myocytes in both the 4-week-old and 9-month-old mice was significantly increased (Fig. 3A). The myocyte cross-section increased from 350 to 781 per μm^2 ($p < 0.01$) in the 4-week-old

transgenic mice. The increase was even larger in the 9-month-old mice (534–2164 per μm^2 , $p < 0.001$).

We also quantitated myocyte dimension by isolating myocytes from the hearts of 4-week-old mice. The cross-sectional area of myocytes from 4-week-old mice was significantly increased (712 per μm^2 in Tg mice compared with 350 per μm^2 in WT mice, $p < 0.001$). All myocytes showed hypertrophy. These data confirm that hypertrophy was present in the hearts of all four lines and four generations as observed in the hearts of Tg mice and that this hypertrophy worsened in older mice (Fig. 3). The cross-sectional areas were quantitated in myocytes from each mouse (WT $n = 5$; Tg $n = 12$) representing all four lines.

Cytokine and Growth Factor Gene Up-regulation Is Associated with Disease Stage in Tg Mice

We examined the relative expression of growth factors and cytokines in the Tg mice representing all four lines, using RPA (Fig. 4, $n = 5$), compared with age-matched WT mice. We studied two age groups of animals: 4-week-old mice, which represented the onset of hypertrophy, and 36-week-old mice, which represented the chronic phase of hypertrophy, during its transition to heart failure. A novel finding was the age-associated changes in expression of different cytokines. As shown in Fig. 4A, at 4 weeks of age, some of the cytokine transcripts were induced in Tg hearts, compared with age-matched WT. Expression of LT- β , TGF- β_2 , and TGF- β_3 were significantly up-regulated in 4-week-old Tg mice compared with age-matched WT ($p < 0.05$). In the 36-week-old Tg mice, interleukin-6, macrophage migration inhibitory factor, tumor necrosis factor- α , interferon- γ , and different isoforms of the transforming growth factor- β family (TGF- β_1 , - β_2 , and - β_3) were significantly elevated, compared with the age-matched WT mice ($p < 0.01$). However, the percentage increase in cytokine transcripts was comparatively higher in 36-week-old Tg than in 4-week-old Tg mice. Interestingly, expression levels of interleukin-6, tumor necrosis factor- α , interferon- γ , TGF- β_2 , and macrophage migration inhibitory factor did not change in the young Tg animals during initiation of hypertrophy compared with the age-matched WT mice (Fig. 4B). These data suggest that the cytokine-/growth factor-mediated hypertrophic process is different in young and old Tg mice, especially during transition to heart failure.

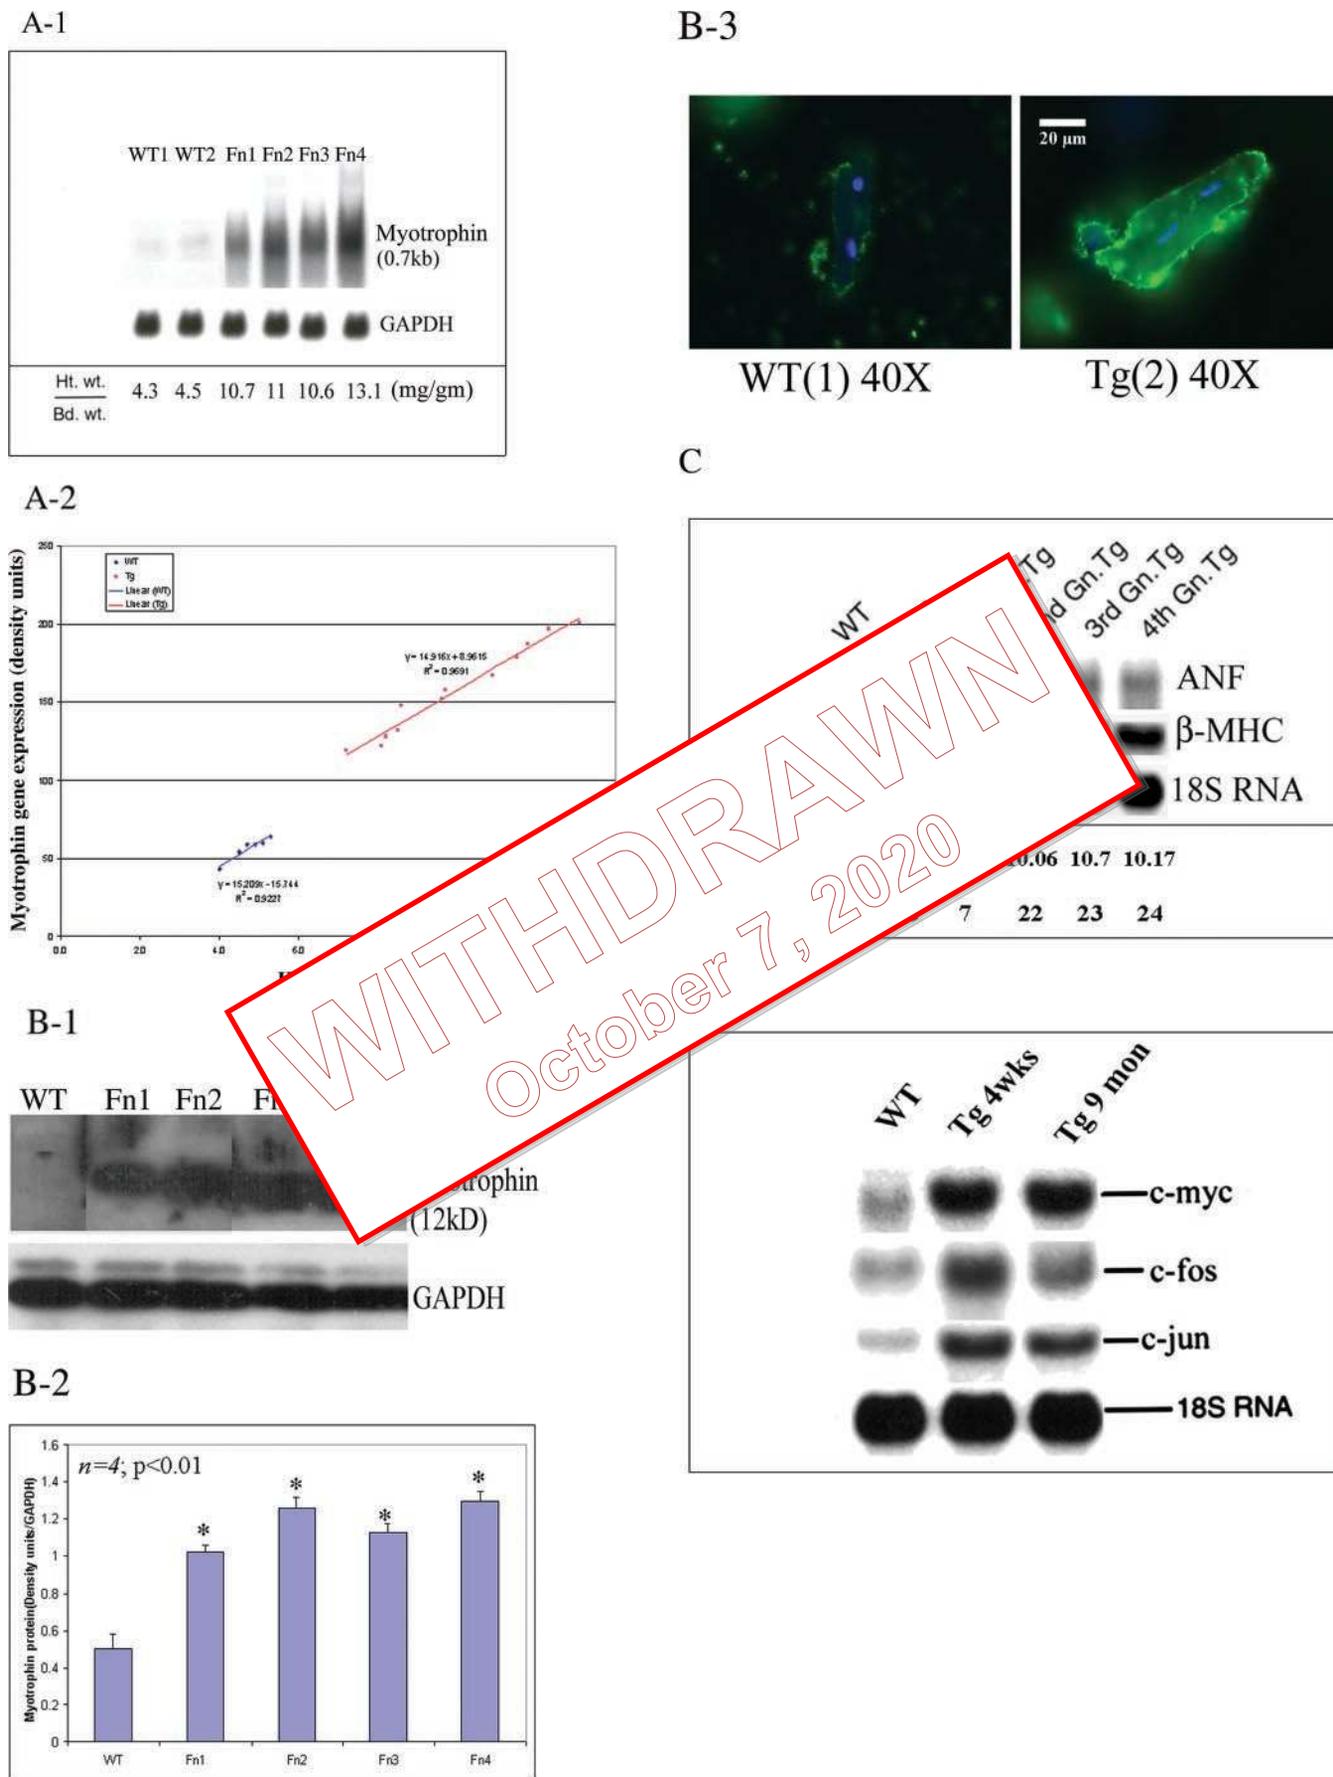

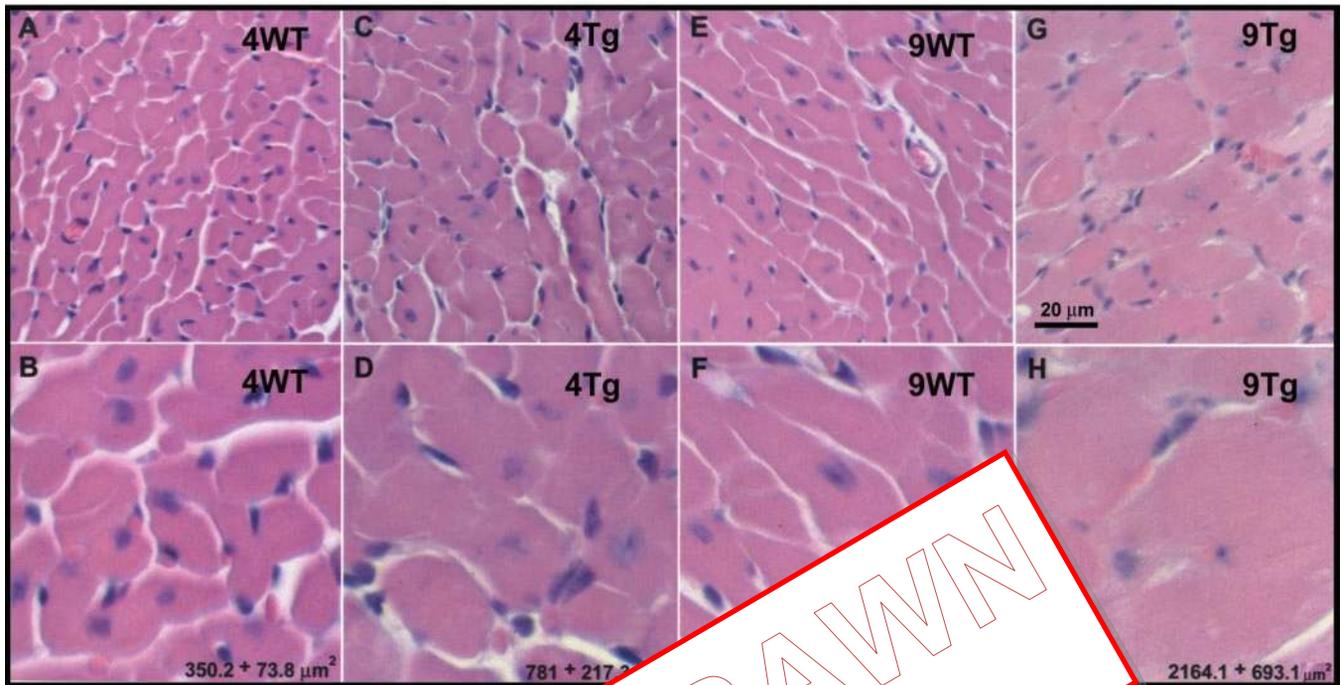

FIG. 2. *A (1)*, Northern blot analysis of myotrophin gene expression in transgenic mice from four founders (Fn1–Fn4, 24 weeks old) compared with age-matched WT. *A (2)*, correlation between myotrophin gene expression (y axis) and HW/BW in Tg and WT mice (between 16 and 24 weeks of age, representing all four lines). A significant correlation was observed between myotrophin gene expression and HW/BW ($r^2 = 0.9227$ for WT mice, and $r^2 = 0.9691$ for Tg mice). *B (1)*, Western blot analysis showing myotrophin protein expression in 24-week-old WT and Tg mice from all four lines

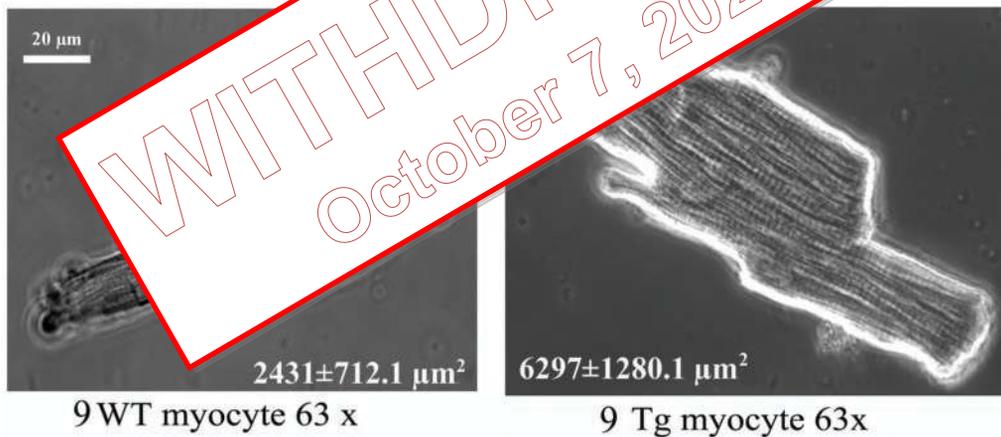

FIG. 3. *A*, quantitation of cross-sectional areas of myocytes in WT and Tg mice ($n = 5$). The *top panel* shows myocytes (stained with hematoxylin and eosin) from 4-week-old mice, WT (*extreme left*) (*A*), and Tg (*C*). *E* depicts 9-month-old WT cells, and *G* shows the myocytes from 9-month-old Tg animals at $\times 63$ magnification. The *lower panel* represents a $\times 2.5$ zoomed picture of the *upper panel*. *B*, myocytes from 4-week-old WT mice; *D*, myocytes from 4-week-old Tg mice; *F*, myocytes from 9-month-old WT mice; *H*, myocytes from 9-month-old Tg mice. A significant increase in the cross-sectional area was observed at as early as 4 weeks of age. This condition persisted and increased during the progression of hypertrophy (for detailed methods, see “Experimental Procedures”). This figure represents five independent experiments. *B*, myocytes isolated from 9-month-old WT (*left panel*) ($\times 63$ magnification) and 9-month-old Tg mice overexpressing myotrophin (*right panel*) ($\times 63$ magnification). The cross-sectional area of myocytes from Tg mice was significantly increased ($2431 \pm 712 \mu\text{m}^2$ to $6297 \pm 280 \mu\text{m}^2$; $p < 0.001$) (for details, see “Experimental Procedures” and “Results”), showing significant hypertrophy in Tg mice ($n = 8$, representing all four lines).

M-mode Echocardiographic Analysis of 9-Month-old Tg Mice Revealed Progression to Heart Failure

M-mode echocardiographic data from the 4-week-old and 9-month-old Tg mice from all four lines are shown in Fig. 5 and Table I. In 4-week-old Tg mice, left atrial diameter (0.20 ± 0.02

versus 0.16 ± 0.005 mm), interventricular septal wall thickness (0.114 ± 0.004 versus 0.1002 ± 0.03 mm), and left ventricular posterior wall thickness (0.122 ± 0.007 versus 0.106 ± 0.004 mm) were significantly elevated, compared with their age-matched WT. Importantly, however, the functional parameter,

(Fn1–Fn4). *B* (2), graph showing quantification of myotrophin protein from WT and Tg mice. *B* (3) shows fluorescein isothiocyanate staining to localize myotrophin in 24-week-old WT and Tg (Fn2) myocytes (magnification, $\times 63$). *C* shows increased expression of ANF and β -MHC transcripts from four generations (Gn1–Gn4), representing all four Tg lines (24 weeks old), compared with age-matched WT mice. Increased expression of ANF and β -MHC transcripts in all four generations confirmed the presence of hypertrophy in Tg mice. *D* shows increased expression of proto-oncogenes in the hearts of young and old Tg mice compared with WT mice.

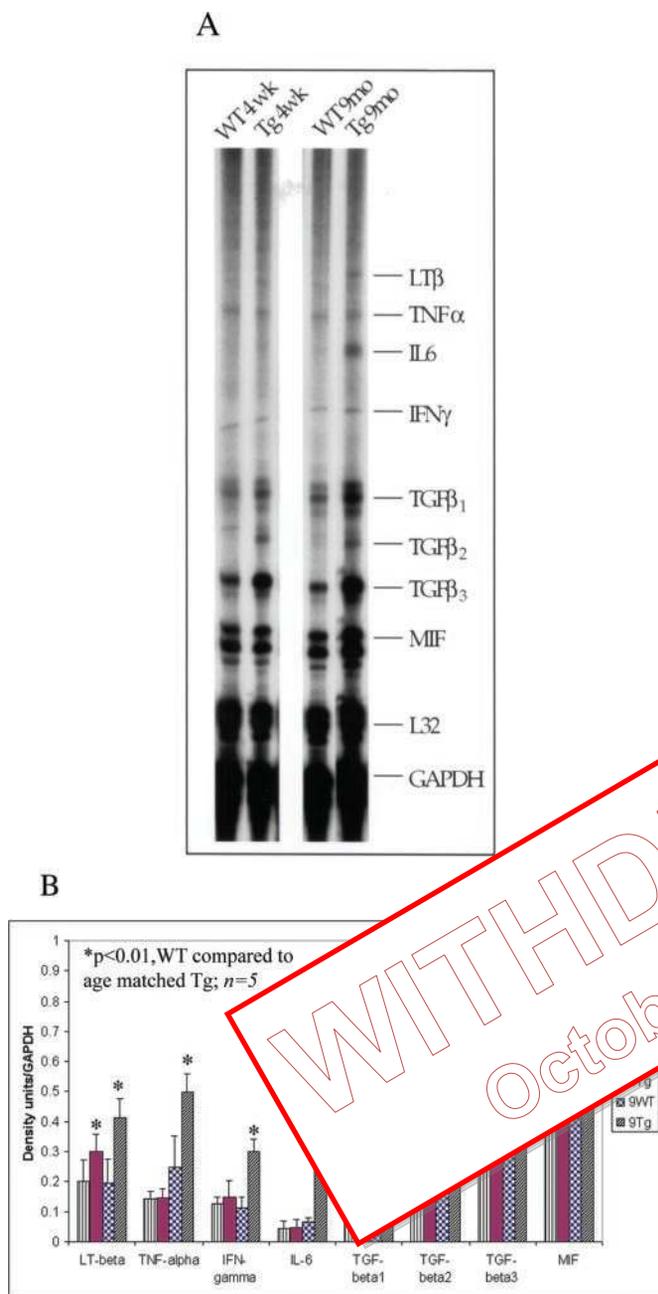

FIG. 4. *A*, a typical autoradiogram of RNase protection assays measuring cytokine expression in hearts from Tg and WT mice. Glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) was used as a loading control. An RNase protection assay was performed in five different Tg and WT mice, representing all four lines. This figure represents a typical finding from five independent experiments. *B*, estimation of the expression pattern of the cytokine transcript level normalized with glyceraldehyde-3-phosphate dehydrogenase in 4-week-old and 9-month-old WT and Tg mice hearts, representing all four lines.

fractional shortening (FS), was not changed in the 4-week-old Tg mice, compared with WT (FS = $50 \pm 0.01\%$ in WT *versus* $48 \pm 0.04\%$ in the Tg group ($p =$ not significant)).

Echocardiographic data from 9-month-old Tg mice revealed statistically significant changes compared with the age-matched control mice: hypertrophied septum (0.105 ± 0.004 *versus* 0.086 ± 0.003 mm, $p < 0.01$), enlarged LV diastolic dimensions (0.375 ± 0.008 *versus* 0.334 ± 0.016 mm, $p < 0.01$), enlarged LV systolic dimensions (0.262 ± 0.037 *versus* 0.150 ± 0.001 mm, $p < 0.02$), and lower FS (26 ± 0.09 *versus* $55 \pm 0.03\%$ in WT, $p < 0.01$). We noted a trend toward left atrial diameter enlargement (0.285 ± 0.05 mm *versus* 0.214 ± 0.022

mm, $p < 0.01$) and increased left ventricular posterior wall thickness (0.090 ± 0.007 *versus* 0.075 ± 0.016 mm, $p < 0.05$) in the Tg mice. Furthermore, we found a large amount of pleural effusion in the Tg mice, which suggested that hypertrophy had already advanced to heart failure.

These data suggest that in the young Tg mice, cardiac function was not compromised, despite the presence of hypertrophy, whereas in the 9-month-old Tg mice, cardiac function was significantly compromised.

DNA Microarray Results

Changes in Gene Expression at the Initiation of Hypertrophy—To identify candidate genes that mediate physiological responses to myotrophin overexpression, oligonucleotide gene array analyses were performed on heart samples from Tg and age-matched WT controls. Cardiac RNAs from five transgenic and five WT animals at each age (4 weeks and 9 months) were used in the gene profiling studies. To identify genes with expression patterns that correlated with initiation of hypertrophy (4 weeks) or transition to heart failure (9 months), two strategies were used. Pairwise comparisons between the experimental animals of individual animal samples were used to identify genes that were up- or down-regulated at a particular time point. In addition, SOM clustering was used to identify genes with similar expression patterns. Genes that were up-regulated within a particular time point by more than 1.8-fold were included in a list of up-regulated genes and are listed as Supplemental Mate-

rials. Genes that were consistently up-regulated in all pairwise comparisons between the 4-week-old Tg mice were compared with the 9-month-old Tg and WT and 4-week-old WT mice (Table II). When just one of the pairwise combinations was significant, 179 genes were induced. Of those, 39 genes were clustered in three major functional categories: extracellular matrix and cytoskeleton, cell signaling, and growth factors/transcriptional regulators. Eleven of 30 up-regulated expressed sequence tags (ESTs) had some assigned function. Among these, sarcolemmal protein SLAP, actin cross-linking protein 7, talin, glycogenin 1, and Cdc 5-like protein were elevated during the initiation of cardiac hypertrophy.

When 4-week-old Tg animals were compared with their age-matched WT animals only, a slightly different picture emerged (Table III). Seventy-four genes were up-regulated in all pairwise comparisons between 4-week-old Tg *versus* WT. These genes were clustered into six functional categories: extracellular matrix, myofibrillar and cytoskeletal protein, cellular signaling factors, growth and transcription factors, cell defense, and protein expression regulators. Forty-five known genes were down-regulated in 4-week-old Tg animals compared with the WT animals. Down-regulated genes were clustered primarily as cell signaling or mitochondrial proteins (Table III).

Changes in Gene Expression during Transition to Heart Failure—Pairwise comparisons were also used to identify genes that decreased in expression when comparing 9-month-old Tg hearts with all other samples (Table II). One hundred thirty-three genes were consistently elevated in failing hearts compared with nonfailing WT or younger Tg hearts. Fifty-one of these genes were functionally clustered into six different categories: cell signaling; growth and transcription factors; extracellular matrix and cytoskeletal protein, cell defense; apoptosis; and protein expression regulators and metabolic enzymes. Of 82 ESTs, only 11 had unknown functions.

Approximately 50 genes were down-regulated in Tg hearts compared with all other samples. Most of these genes were

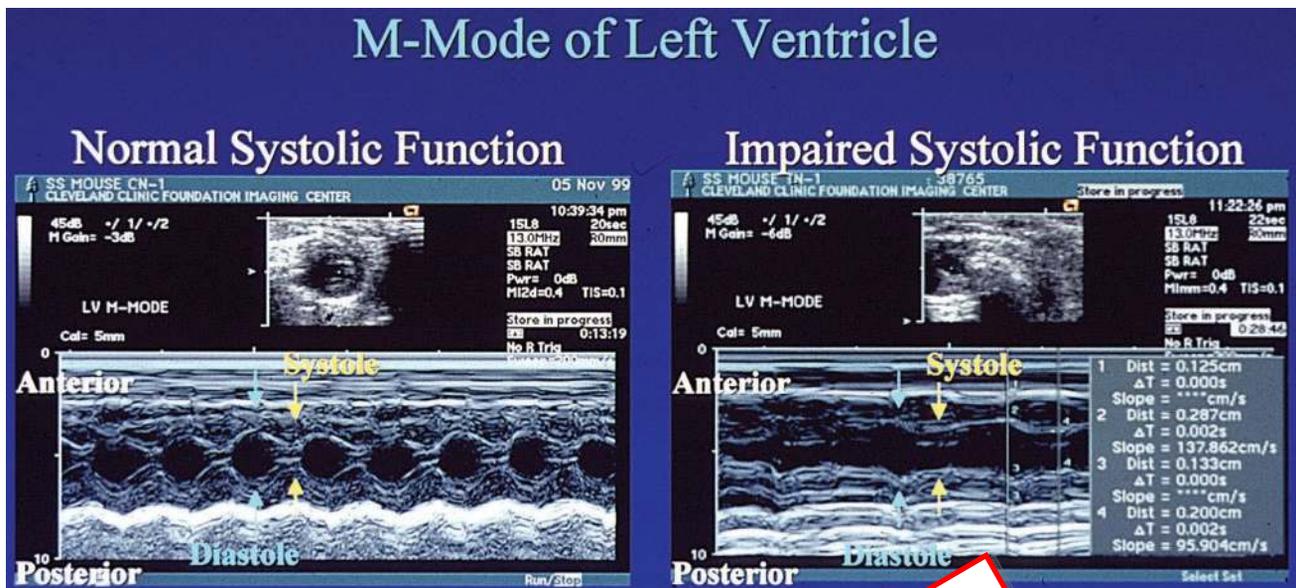

FIG. 5. A typical M-mode echocardiogram from the 36-week-old WT and Tg mice. Twenty echocardiograms were performed on different mice from all four lines, showing similar changes. Several echocardiogram parameters from 4-week-old mice hearts (WT and Tg) are tabulated in Table I.

identified in the aforementioned pairwise comparisons and represented several functional groups: extracellular and cytoskeleton proteins, cellular signaling, or mitochondrial enzymes. Twenty-one down-regulated ESTs included AP-4-related protein 1, H1.2, mitochondrial ribosomal protein MRPs15, and flavoprotein, and transcription elongation factor 1.

Pairwise comparison of 9-month-old Tg and 4-week-old Tg heart samples yielded 197 genes that were consistently up-regulated. These genes were grouped into several functional categories: cell cycle regulators, cytoskeleton or protein synthesis, cell growth and transcription factors, cell defense proteins, and cell signaling. Proteins involved in cell division and cell cycle were identified as known ESTs among the up-regulated genes. Increased expression in failing mouse hearts was also seen in the up-regulated genes, 206 genes were consistently down-regulated across the pairwise comparisons. For example, genes were clustered into functional groups, including cell signaling, matrix and cytoskeleton, or mitochondrial enzymes. Of 159 down-regulated ESTs, 16 had known functions (Table III).

Fig. 6 summarizes SOM clustering analysis of the maximally changed genes in 9-month-old Tg versus all as well as 4-week-old Tg versus all. When SOM clustering was performed using absolute gene expression values from all samples from 9-month-old Tg animals compared with either age-matched WT or 4-week-old WT or Tg mice, definitive clusters of candidate genes up- or down-regulated during the transition from hypertrophy to heart failure emerged (Fig. 6, a and b). Those maximally up-regulated include fibronectin, VCAM1, slow myosin heavy chain, matrix metalloproteinase 3, ceruloplasmin, apolipoprotein D, and MRPs8. Approximately 80 genes were expressed at a higher level in three 4-week-old Tg animals when compared with all other animals (Fig. 6c). Included within this group were skeletal muscle actin, MLC3F, calsequestrin, immediate early genes, SLAP, glycogenin, skeletal muscle tropomyosin, talin, and disintegrin. All genes from this cluster were identified in the pairwise comparisons noted above. Interestingly, SOM analysis did not identify clusters of genes consistently down-regulated at this early developmental time point (data not shown).

Transition from Heart Failure and Hypertrophy Versus Young Tg (4-week-old) versus 9-month-old Tg. To identify genes that specifically initiate the transition from hypertrophy to heart failure. Pairwise comparison of 9-month-old Tg and 4-week-old Tg samples identified 30 cardiac genes that were specifically up-regulated in Tg compared with WT animals (thereby excluding age-regulated genes) (Table IV). Of these up-regulated genes, 44 genes were classified as extracellular matrix and cytoskeleton, cell growth and transcription factors, cell signaling factors, cell defense, apoptotic, protein expression regulators, or mitochondrial proteins. Eleven of the ESTs with known functions included calcium-binding protein A15, casein kinase I, insulin-like growth factor 3, and Rab-6 (a *ras* oncogene family protein).

Similar pairwise comparisons identified 30 cardiac genes down-regulated in 9-month-old Tg animals compared with 4-week-old Tg animals. These genes clustered into several functional groups: extracellular matrix and cytoskeleton proteins, mitochondrial enzymes, cell signaling factors, or cell cycle regulators. Fifteen known ESTs in this group included cyclophilin D, tropomyosin 5, exportin 1, and Ras-related protein RAL1.

DISCUSSION

This study reinforces the proofs we have previously presented that myotrophin is a significant causal factor in the hypertrophy/heart failure continuum. Data presented here document the effects of myotrophin protein overexpression at molecular, cellular, morphological, and functional levels in a specially developed line of Tg mice. These data indicate that myotrophin overexpression initiates cardiac hypertrophy, eventually progressing to heart failure, a process associated with changes in expression of proto-oncogenes, ANF, β -MHC, and cytokines. Importantly, using this model and the new tools of state-of-the-art DNA microarray analysis (Fig. 6 and Tables II and III), we have elucidated patterns of gene up-regulation and down-regulation that may be involved during initiation of cardiac hypertrophy and progression to heart failure in humans.

WITHDRAWN
October 7, 2020

We documented several novel mechanistic changes that occur during the transition from hypertrophy to heart failure. We confirmed that myotrophin overexpression resulted from increased myotrophin mRNA and protein levels in all lines and generations of Tg mice (Fig. 2). Importantly, the increase in myotrophin triggered a significant increase in cytokines and growth factors such as LT- β , tumor necrosis factor- α , interfer-

on- γ , interleukin-6, TGF- β ₁, TGF- β ₂, TGF- β ₃, and macrophage migration inhibitory factor, in 9-month-old Tg mice, when chronic hypertrophy advanced to heart failure (Fig. 4), whereas, at 4 weeks of age, three genes (LT- β , TGF- β ₂, and TGF- β ₃) were up-regulated in Tg mice, compared with the age-matched WT. Echocardiographic data showed significant hypertrophy of left ventricle and septum (asymmetric hyper-

TABLE III
Changes in gene expression at the initiation of hypertrophy (4-week-old Tg (4 Tg) versus 4 WT) and during transition to heart failure (9-month-old Tg (9 Tg) versus 9 WT)

Accession no.	9 Tg versus 9 WT (n = 5)	Mean -fold change	Accession no.	4 Tg versus 4 WT (n = 5)	Mean -fold change
Up-regulated genes					
Cell signaling					
D16497	Natriuretic peptide precursor B	2.3	X12973	MLC3F gene for myosin alkali light chain	2.0
K02781	Natriuretic peptide precursor A	5.1	U93291	Skeletal muscle calsequestrin	1.8
M84487	Vascular cell adhesion molecule 1	3.1	U03419	Procollagen α 1 type 1	2.5
X66449	Calcyclin	2.7	X66976	Collagen 8a1	2.3
Z68618	Transgelin	3.2	X13986	Minopontin	12.3
U07982	Endothelin 1	2.3	M28729	Tubulin α 1	1.8
Extracellular matrix and cytoskeletal proteins					
X13986	Minopontin	70.0	AF020185	Protein inhibitor of nitric-oxide synthase	2.3
X58251	Procollagen type 1 alpha 2	3.1	D16497	Natriuretic peptide precursor type B	2.4
M18194	Fibronectin	3.5	M84487	VCAM 1	2.3
X70854	Fibulin	2.6	X77952	Endoglin	1.9
AJ223362	Slow myosin heavy chain β	3.1	M69260	Lipocortin 1	1.9
X66402	Matrix metalloproteinase3	4.1	Cell defense		
Protein expression					
X82648	Apolipoprotein D	7.3	X15591	Cytoskeleton-associated protein 2 α	3.9
M83218	Calcium binding protein, MRP-8	8.1	U69491	Interleukin 1 receptor activator	1.5
Z11911	Glucose-6-phosphate dehydrogenase	6.2	J03520	Interleukin 1 receptor 2	4.1
Growth factors and transcription factors					
X81581	Insulin-like growth factor protein	8.9	U49430	Interleukin 1 receptor 2	2.5
M61007	CCAAT/enhancer-binding protein	2.1	G03001	Interleukin 1 receptor β	2.8
M32745	Transforming growth factor- β 3	2.1	M19681	Interleukin 1 receptor 2	1.8
Apoptosis and cell division

TABLE IV
Comparison of gene expression between heart failure and initiation of hypertrophy: Tg (9 months old) versus Tg (4 weeks old) (n = 5)

Accession no.	Gene description	Mean -fold change
Up-regulated genes		
Extracellular matrix and cytoskeletal proteins		
AF061272	C-type lectin	20.3
M18194	Fibronectin mRNA	2.5
X66402	Matrix metalloproteinase 3	4.1
AB007848	Bone matrix protein osteomodulin	2.7
U04541	α -Tropomyosin, slow	2.5
X67348	Procollagen type X, α	2.3
Growth and transcription factors		
X81580	Insulin-like growth factor-binding protein 2	2.7
U17291	Transcription factor AP2	3.1
Cell signaling		
U12884	Vascular cell adhesion molecule 1	2.9
U59758	p53 variant mRNA	1.8
U28423	Protein kinase inhibitor p58	4.6
M21856	Cytochrome P450	1.6
U40930	Oxidative stress-induced protein	2.6
AF047838	Calcium-sensitive chloride conductance protein 1	4.4
Cell defense		
AF019048	Tumor necrosis factor superfamily member	3.1
M33960	Plasminogen activator inhibitor (PAI-1)	6.4
M17015	Lymphotoxin A	
Protein expression		
M83219	Intracellular calcium-binding protein	1.8
U08373	Calmegin (Ca ²⁺ -binding protein)	2.3
M70642	Fibroblast-inducible protein	1.8
Apoptosis		
AF041054	Nip3 (Bcl2-binding protein 3)	2.4
AB019600	Caspase 8	1.9
ESTs		
AI842277	EST	3.1

trophy) in 36-week-old Tg mice hearts, a typical change observed in human hypertrophy. Mice afflicted with hypertrophy also had severely compromised cardiac function associated with pleural effusion, a common occurrence during human heart failure. However, this compromised function did not occur in the hypertrophied hearts of young 4-week-old Tg mice despite presence of hypertrophy. Our data also suggest that atrial enlargement arises from mitral and tricuspid valve regurgitation, which occurs because the ventricular cavity enlarges, causing an incomplete sealing in these valves. This cluster of symptoms mimics human cardiomyopathic hypertrophy with end-stage heart failure. Although other Tg models have been reported (14, 15), none have studied the progression

of hypertrophy that advances to heart failure in the manner we have described. Previously, using isolated myocytes, we have shown that the mode of action of myotrophin protein is mediated through protein kinase C and NF- κ B signaling pathways (16). This *in vivo* model, overexpressing myotrophin, provided us with the opportunity to dissect out the role of myotrophin-induced signaling pathways for the initiation process of cardiac hypertrophy and its progression to heart failure. Work is in progress to determine protein kinase C and NF- κ B cascade in Tg hearts at 4 weeks, 16 weeks, and 9 months compared with their age-matched WT.

This model provided the opportunity to further the genome-wide screening of cardiac tissue as a tool to identify new genes

phase and during the transition of hypertrophy to heart failure. Comparison of the gene array data between the initiation of hypertrophy and its transition to heart failure involves differential activation of functional gene clusters. Up-regulation of growth factors, calcium-binding proteins, proteins regulating programmed cell death, and extracellular/cytoskeletal proteins as well as down-regulation of mitochondrial proteins and cytoskeletal/myofibrillar proteins mark the transition phase, which is associated with severely compromised heart function, thereby differing from the mechanisms of the initiation process of hypertrophy as well as those operating in nonfailing WT hearts.

The intricate, multifaceted process of heart failure, especially its transition from longstanding hypertrophy to heart failure, involves many factors. Eventual heart failure is probably the result of cross-talk between neurohumoral mechanisms and growth factors. Our new genetic data, added to our prior findings based on molecular and biochemical data, convincingly demonstrate that myotrophin is a factor that not only initiates hypertrophy but is also associated with the progression to heart failure. We expect that this new mouse model will provide the key to elucidate further molecular mechanisms that occur during advancement of hypertrophy to heart failure and will facilitate the design of effective therapies.

Acknowledgments—The gene array studies were conducted in the University of Toledo Center for Molecular Biology. We thank Dr. Jeff Robbins of University of Cincinnati for α -MHC promoter, Dr. M. Chawla-Sarkar of the Taussig Cancer Center for assistance

RPA, Christine Kassuba for editorial assistance, and JoAnne Holl for expert secretarial support.
