### ABSTRACT

Genetic improvement through induced mutation has been very effective in improvement of crops. Seeds of three popular chickpea variety namely BGM 408, B115 and JG 315 were treated with 10,20 and 30 kR of gamma rays. Then treated seeds with their respective control(0 kR gamma rays) were sown in the field of Calcutta University experimental farm,Baruipur (with no salinity) in three consecutive years to raise  $M_1$ ,  $M_2$  and  $M_3$  generations respectively. Some  $M_3$  lines having higher yield potential were subjected to grow as  $M_4$  lines in salt stressed field ( $5\text{-}7\text{ds m}^{-1}$ ) of Hingalganj, South 24 Parganas. Finally, some promising salt tolerant lines with improved seed yield were selected which have a good promise for coastal saline belt after releasing as a variety.

**Key words:** Chickpea, Gamma rays, Induced mutation, Salinity, Seed yield.

### INTRODUCTION

Mutation breeding is a very good tool to create new genetic variability. Mutation breeding offers a great scope and promise for generating useful variability (Sinha and Lal,2007). Many useful mutants have been evolved in pulse crop through mutation breeding which fulfil desirable breeding objectives. In leguminous crop, such as chickpea, improved cultivars are developed through conventional breeding methods. But in a global scale little concentrated efforts have been made for its genetic improvement. Induced mutation can play role in renewal as well as augmentation of the natural variability to some extent. Extensive studies on induced variations through mutation in cereal crops have been undertaken, but very few reports are available in chickpea (Srivastava *et al.*,1973;Kharkwal,1998),which is covering more than 50% area among the pulse crops. Objective of the present study was to create variability in an existing chickpea population in favor of salinity tolerance. Salinity tolerance was measured in terms of yield and yield related traits under saline stress condition. Effective mutagenesis means, production of maximum desirable changes accompanied by least undesirable changes (Pathania and Sood,2007).Gamma rays are known to influence plant growth and development by inducing cytological, genetical, morphological, physiological and biochemical changes (Gunckel and Sparrow,1961). Acharya *et al.*, (2007) made improvement in medicinal and nutritional properties of fenugreek.

### MATERIALS AND METHODS

Three popular chickpea genotypes namely BGM 408,B 115, and JG 315 were selected for applying the mutagenic treatment. Physical mutagens, gamma rays was used as mutagenic treatment. Dry seeds of 10-12% moisture content were exposed to 10, 20 and 30kR doses of gamma rays. The irradiation was done at the rate of 1.087kR /min in the gamma irradiation cell of Saha Institute of Nuclear Physics (SINP), Salt Lake. The treated seeds including control(without mutagenic treatment)were sown in randomised block design with three replications as  $M_1$  in the Calcutta University experimental farm at Baruipur, South 24 paraganas(normal location,without salinity) in the year 2009-10.Two rows were used for each treatment and also for the control. Distance between row to row was of 30cm and plant to plant was 20cm. Normal cultivation practices were followed without application of fertilizer. Several characters like germination and survival percentage, plant height, branches/plant, pods/plant, pod length, seeds/pod,100 seed weight, seed yield/plant and harvest index were taken. All healthy and normal looking plants for each treatment were advanced to raise  $M_2$  generation next season in the same location. Cultivation practices were followed as in  $M_1$  generation. The plants were harvested separately and after harvest the similar parameters like  $M_1$  generation were recorded and some  $M_2$  plants were selected on the basis of yield and yield related characters. They were referred as lines. Thus  $M_3$  generation comprises of number of lines from  $M_2$  generation for each treatment for each of the three genotypes.  $M_3$  lines were evaluated based on the same parameters as in

M<sub>1</sub> Some promising M<sub>3</sub> plants were selected on the basis of yield and yield related attributes which were referred as M<sub>4</sub> lines. They were grown in the salinity prone (5-7ds m<sup>-1</sup>) farming field of Hingaljanj, South 24 paraganas, West Bengal in *rabi* season of 2012-2013. Experimental design and inter culture operations like M<sub>1</sub> generation were followed and parameters like M<sub>1</sub> generation were recorded. Finally some salt tolerant high yielding mutant chickpea lines were selected.

**RESULTS AND DISCUSSION**

**M<sub>1</sub> generation:** Mean, sd and cv were calculated and presented in Table 1. Among the parameters studied in M<sub>1</sub> generation, germination and survival percentage, plant height, pods per plant, 100 seed weight, seed yield per plant and harvest index were gradually reduced with increasing dose of gamma rays. Reduction of germination percentage was also recorded by Sharma and Sharma (1982) in lentil and Khan *et al.*, (1993) in mungbean. Such decrease in germination in high dose of gamma rays in chickpea may be due to enhance production of active radicals which may cause seed lethality. Reduction of plant height was also reported in number of pulse crop in M<sub>1</sub> generation by Sinha and Lal (2007) in lentil and Khan *et al.*, (1993) in mungbean. Such decrease in germination in high dose of gamma rays in chickpea may be due to enhance production of active radicals which may cause seed lethality. Sinha and Bharati (1990) in blackgram, Popa (1991) in pea, Singh and Yadav (1991) in greengram, Ahmed and Yaqoob (1993) in mungbean reported reduction of plant height with increasing dose of gamma rays. It was assumed that plant height was reduced due to inhibition of certain growth hormones. Sinha and Lal (2007) reported gradual reduction of seed yield in M<sub>1</sub> generation in Lentil. On the contrary branches/plant, pod length and seeds /pod were found unaffected or less affected.

The above discussion by and large demonstrates the potentiality of mutagenic treatment for inducing variability in M<sub>1</sub> generation. But the magnitude of variation differed for all the characters in either of the genotype. It was noticed that pods/plant and seed yield/plant were the most drastically affected traits in M<sub>1</sub> generation.

**M<sub>2</sub> generation:** Mean, sd and cv were calculated and given in Table 2. Similar trend of results like M<sub>1</sub> generation were noticed in M<sub>2</sub> generation also. The better performing M<sub>2</sub> lines were selected on the basis of mean yield and yield related characters and sown in field to raise M<sub>3</sub> generation.

**M<sub>3</sub> generation-Selected M<sub>3</sub> lines:** Several individual plants were identified from M<sub>3</sub> generation on the basis of yield and yield related traits (Table 3). The treated individuals registered plant height more or less similar to that of the control. Maximum plant height was recorded in 10 and 20 kR doses for all the genotypes. The maximum branch number was recorded for individuals from different treatment doses in all the genotypes. The pods/plant also revealed similar results. The highest pod number was from 20kR dose treated

**Table 1:** Mean, Standard deviation (sd) and coefficient of variation (cv) of different agronomorphological characters in M<sub>1</sub> generation

| Variety | Treatment | G% S%   | Plant height |       | Branches/plant |       | Pods/plant |      | Pod length |       | Seeds/pod |       | 100 seed weight |       | Seed yield/plant |      | Harvest index |       |       |      |       |       |      |       |       |       |       |       |

- cv=Coefficient of variation

individual for JG 315 and 20kR line for BGM 408. In case of pod length and seeds/pod no huge variation was observed. There was not much variation for the 100 seed weight for the treated and the non-treated individuals. But in the 10 kR dose of the genotype JG 315 highest 100 seed weight was recorded. Maximum seed yield per plant was produced by many treated lines from 10,20 and 30 kR in all of the genotypes. These selected individual were tested for salinity tolerance in the saline prone areas of Hingaljanj in the next season and they were referred as M<sub>4</sub> lines.

#### M<sub>4</sub> Generation

**i. Grouping of mean :** Observations are presented in Table 4. In case of plant height almost all of the treatments showed negative shift, except 20 kR dose of JG 315. In case of branches/plant 30 kR dose of B115 and 20 kR dose of JG 315 exhibited positive shift. Positive shift in pods/plant was only observed in 20 kR and 30 kR dose of JG 315. Pod length exhibited no change from mean in higher frequency. In case of Seeds/pod 20 kR dose of JG 315 exhibited positive shift in higher frequency. Among all the characters studied 100 seed weight disclosed positive shift in appreciably higher frequency in almost all of the treatments in all the genotype, suggesting the occurrence of lines of higher seed mass potentiality. In case of seed yield 20 kR dose of JG 315 exhibited positive shift from mean indicating that selection is possible from these lines. Harvest index mostly negatively shifted from mean, indicating that biomass production was greatly hampered. Such shift in mean was observed in Lentil (Sharma and Sharma, 1982).

**ii. Selection and characterization of M<sub>4</sub> selected lines :** Several individual were identified from the selected superior lines of M<sub>4</sub>. Different plant attributes including seed yield per plant of these individuals are presented in Table 5. Majority of the individuals were from 10kR and 20kR treated population. These individuals produced very high seed yield per plant than their respective controls. Five individuals were identified from 20 kR dose of JG 315, two individuals were identified from 10 kR dose of B 115 and two individuals from 10 kR dose of BGM 408. So, total nine individuals were selected. Most of the treated individual showed more number of branches/plant, pods/plant and seed yield over the control. The lower dose of gamma radiation would thus likely to create useful and desirable mutants with high seed yield potentiality in chickpea genotypes. The usefulness of low dose of gamma radiation was also reported by Singh *et al.* (1998), Chopra (2005) and Bentota, (2006). So these individuals have a great potentiality for cultivation in coastal areas after releasing as a variety. Thus in a nutshell the mutagenic treatments had pronounced effects on the yield attributing traits and it shows signs of improvement than that of control.

**Table 3:** Selected promising M<sub>3</sub> lines: Their agro-morphological characters and seed yield

| Genotypes | Old line                                      | New Line                       | Dose    | Characters        |                |            |                |           |                      |                |               |
